Abstract: The LiquidJet PES apparatus is a specialized end-station at the synchrotron radiation facility BESSY II, Berlin, for studying the electronic structure of liquid water, aqueous and non-aqueous solutions with soft X-ray photoelectron spectroscopy. Targets are liquid microjets that are introduced into a vacuum chamber via a ~ 20 µm glass capillary.

1 Introduction

Fundamental interactions between solute electronic structure and highly volatile liquid solutions, especially water, which are essentially the key to chemical reactivity, have remained poorly understood. Only with the introduction of the liquid microjet technique, and its first application in conjunction with synchrotron radiation about a decade ago, has liquid-phase photoelectron spectroscopy evolved as a research field.

The LiquidJet PES station presented here has been designed to measure (photo)-electrons from a liquid microjet that is introduced into the main interaction chamber via an 18-25 µm glass capillary, forming a free liquid surface in vacuum. One 1500 l/s turbo pump and several LN₂ cold-traps keep the pressure on the 10⁻⁴ mbar level under operation conditions. Photoelectrons are detected by a robust and compact SPECS EA10 hemispherical analyzer with a replaceable 100-500 µm skimmer orifice, acting as a pressure barrier between the main chamber and the electron analyzer. The small distance of <0.5 mm between the jet and the orifice assures that detected electrons have not suffered from inelastic scattering with water gas-phase molecules near the jet surface. Typical energy resolutions of the hemispherical energy analyzer are 100 meV at 10 eV pass energy (used for valence photoelectron measurements at
170 – 200 eV photon energy) and ~ 200 meV at 20 eV pass energy (used for core level and resonant photoelectron measurements at higher photon energies up to 1500 eV).

Figure 1: View of the LiquidJet PES endstation. The vacuum chamber is rotatable to measure under different angles between the polarization vector of the incident light and the detector.
2 Instrument application

Typical applications are:

- Systems: organic and inorganic molecules, and nanoparticles in water
- Electronic structure of liquid water and aqueous solution
- Solute and solvent electron binding energies
- Core-level chemical shifts, lowest ionization energies and reorganization energies
- Structure and composition of solution interfacial structure; depth profiles
- Chemical equilibria at the solution surface
- Ultrafast relaxation processes induced by core-level ionization/excitation
- Ultrafast energy and charge transfer in hydrogen-bonded systems
- Resonant and non-resonant autoionization (Auger) electron spectroscopy
- Electron scattering processes in water and in solution
- Angular-resolved PE spectroscopy from aqueous solution

Methods:

- (Resonant and off-resonant) X-ray photoelectron spectroscopy (XPS, RPES)
- Auger-electron X-ray spectroscopy
- Angular resolved photoelectron spectroscopy (ARPES)
- Partial electron yield measurements (PEY-XPS)

Table 1: Technical parameters of the LiquidJet PES endstation
4 Spectra

Figure 3: Examples of valence and core-level photoelectron spectra: from neat water (blue, $E_{\text{phot}} = 200$ and 600 eV), from 1 molar NaI aqueous solution (red, $E_{\text{phot}} = 200$ eV), from 1 M imidazole aqueous solution at pH = 10.5 (green, $E_{\text{phot}} = 200$ and 480 eV) and at pH = 2.6 (cyan, $E_{\text{phot}} = 480$ eV), and from 1 M NiCl$_2$ aqueous solution (orange, $E_{\text{phot}} = 200$ and 1000 eV). Important solute peaks are labeled and highlighted.
Figure 4: Example for an RPES measurement: Resonant spectra from a 0.8 M TiCl$_3$ aqueous solution are obtained when sweeping the photon energy across the Ti$^{3+}$ L$_{2,3}$ XA edges. Auger-electron emission ranges corresponding to 2p-3p3d and 2p-3d3d are labeled. 3p-XA and 3d-XA are abbreviations used in labelling the corresponding PEY-XA spectra. Figure (A) is a waterfall-spectrum representation, showing the electron distribution curves measured as a function of electron kinetic energy. In (B) the same data is presented as a contour map (photon energy versus kinetic energy of the electrons, and electron signal is presented by color; intensity increases in the order of blue, green, yellow, brown, and white.
